Most failed medicines come from factories we already knew about.

Public medicine buyers in India (state medical-services corporations, hospitals, the Jan Aushadhi scheme) cannot see a supplier's national quality record before they buy, because CDSCO's failure alerts are scattered across monthly PDFs and a portal, the same factory is spelled hundreds of ways, and nothing connects them to buyers' purchasing systems. As a result, repeat failures reach patients: 64.9% of failed batches come from factories already on the national list.

Why it matters

3,104
drug samples NSQ in 2024–25 (Lok Sabha)

24
children dead after Coldrif syrup, as of 15 Oct 2025 (ETV Bharat)

40
failures from one supplier, banned a year, then reinstated (DTE)

0
buyer ERPs that read CDSCO's national failure list

What exists, and the gap

CDSCO publishes every failed batch, but as monthly PDFs and a portal, with no factory identity and no API. Buyers' ERPs (DVDMS, e-Aushadhi) handle purchase and testing but never read the alerts. Risk-based inspection, started after the 2025 deaths, serves regulators, not the buyer about to order. **The evidence is public, but it isn't joined up by factory, isn't trusted enough to act on, and isn't there at the moment of purchase.**

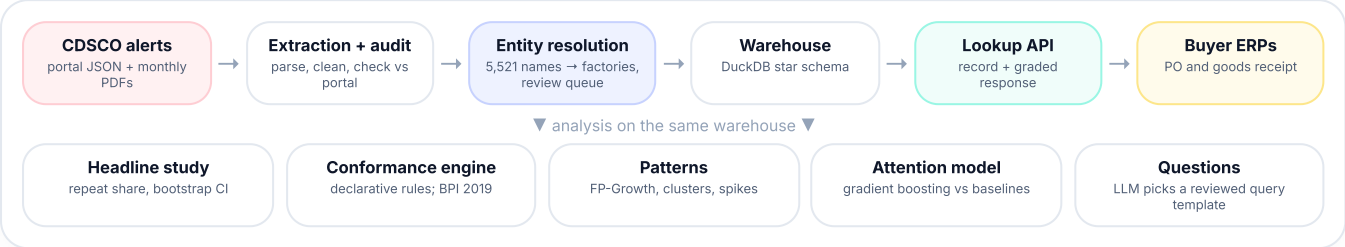

What we found in nine years of alerts (real data)

- **64.9%** of 6,442 failed batches came from a factory with an earlier alert (95% CI 62.2%–67.4%).
- The next failure comes about **8 months** after the first. **53%** of repeats are found by a lab new to that factory.
- **48%** of failures come from 10% of factories.
- With exact name matching it would look like **4.2%**, because one factory is spelled up to 14 ways.
- **Honest limit:** Coldrif, Maiden and Kaysons had **no** national alert before their incidents, so the memory must also take state-lab and buyer results.

OUR SOLUTION

A national quality memory, and a lookup every buyer's ERP can call

DawaDrishti turns nine years of CDSCO alerts into one national quality memory, with a lookup that any buyer's ERP can call at purchase order and at goods receipt. It returns the factory's public record and a graded answer on what to do now, and every claim is tested against a baseline. Not another ERP, and not a blacklist.

What it does

- **Public lookup:** every published failure per factory, with as-of date, data limits and a correction link. No predictions.
- **Buyer view:** graded response (pause / test every batch / prefer alternatives) plus supply concentration.
- **Goods receipt:** a batch already on the national list is held on arrival. Issue is blocked until cleared.
- **Regulator:** where to sample next; a conformance engine for buyers' event logs.

How we know (against baselines)

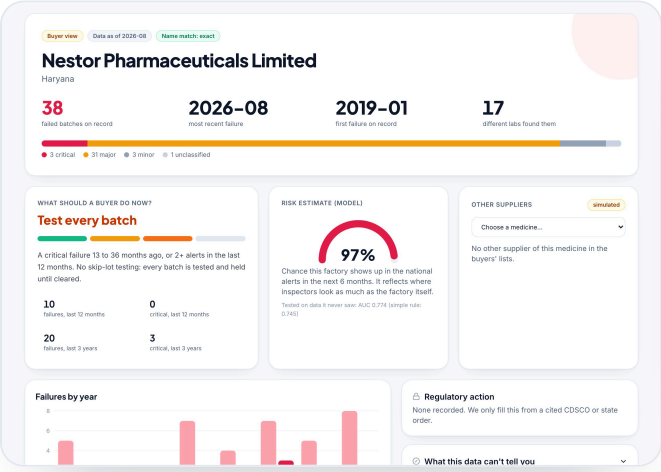

Check	Result
PDF reader vs CDSCO portal	96.9% rows
Name matching precision (held out)	1.00
Next-6-month alerts: model vs best rule	0.774 vs 0.745
Same, found by a new lab	0.765
Real SAP log (BPI 2019): counts reproduced	4 / 4
Risk-first testing (simulated)	69% vs 28%

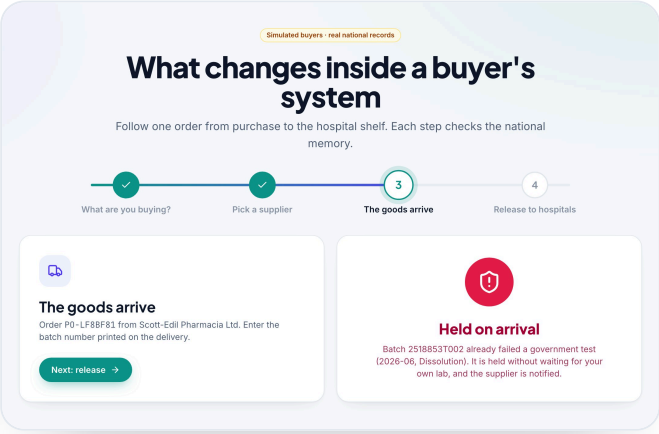

Responsible by design

Records only on public pages, enforced by the API. Every figure is dated. A correction route on every record. No guessed identities. The LLM only picks reviewed query templates. Simulated data is labelled.

Next steps

3 months: human label review; state labs and buyers send results in. **6 months:** pilot with one state corporation's ERP. **12 months:** DVDMS / e-Aushadhi connector and a licence master for true alternatives.
